

Finding Power of Factorial Divisor

Table of Contents

- [Prime \$k\$](#)
 - [Implementation](#)
- [Composite \$k\$](#)

You are given two numbers n and k . Find the largest power of k x such that $n!$ is divisible by k^x .

Prime k

Let's first consider the case of prime k . The explicit expression for factorial

$$n! = 1 \cdot 2 \cdot 3 \dots (n - 1) \cdot n$$

Note that every k -th element of the product is divisible by k , i.e. adds $+1$ to the answer; the number of such elements is $\left\lfloor \frac{n}{k} \right\rfloor$.

Next, every k^2 -th element is divisible by k^2 , i.e. adds another $+1$ to the answer (the first power of k has

already been counted in the previous paragraph). The number of such elements is $\left\lfloor \frac{n}{k^2} \right\rfloor$.

And so on, for every i each k^i -th element adds another $+1$ to the answer, and there are $\left\lfloor \frac{n}{k^i} \right\rfloor$ such elements.

The final answer is

$$\left\lfloor \frac{n}{k} \right\rfloor + \left\lfloor \frac{n}{k^2} \right\rfloor + \dots + \left\lfloor \frac{n}{k^i} \right\rfloor + \dots$$

The sum is of course finite, since only approximately the first $\log_k n$ elements are not zeros. Thus, the runtime of this algorithm is $O(\log_k n)$.

Implementation

```
int fact_pow (int n, int k) {  
    int res = 0;  
    while (n) {  
        n /= k;  
        res += n;  
    }  
    return res;  
}
```

Composite k

The same idea can't be applied directly. Instead we can factor k , representing it as $k = k_1^{p_1} \cdot \dots \cdot k_m^{p_m}$. For each k_i , we find the number of times it is present in $n!$ using the algorithm described above - let's call this value a_i . The answer for composite k will be

$$\min_{i=1 \dots m} \frac{a_i}{p_i}$$
